Traditional HMER

- Encoder-decoder architecture
- Encoder: Input Sequence \rightarrow Output Context Vector in fixed length
- Decoder: Context vector \rightarrow Output Sequence
- Weakness: Accuracy not guaranteed for complicated formula or long markup sequence

Structure of CAN

Feature Map

$$Q = \sigma(W_1(G(\mathcal{H})) + b_1),$$

$$S = Q \otimes g(W_2 Q + b_2),$$

Enhanced Feature

→ 1×1 Conv + Sigmoid

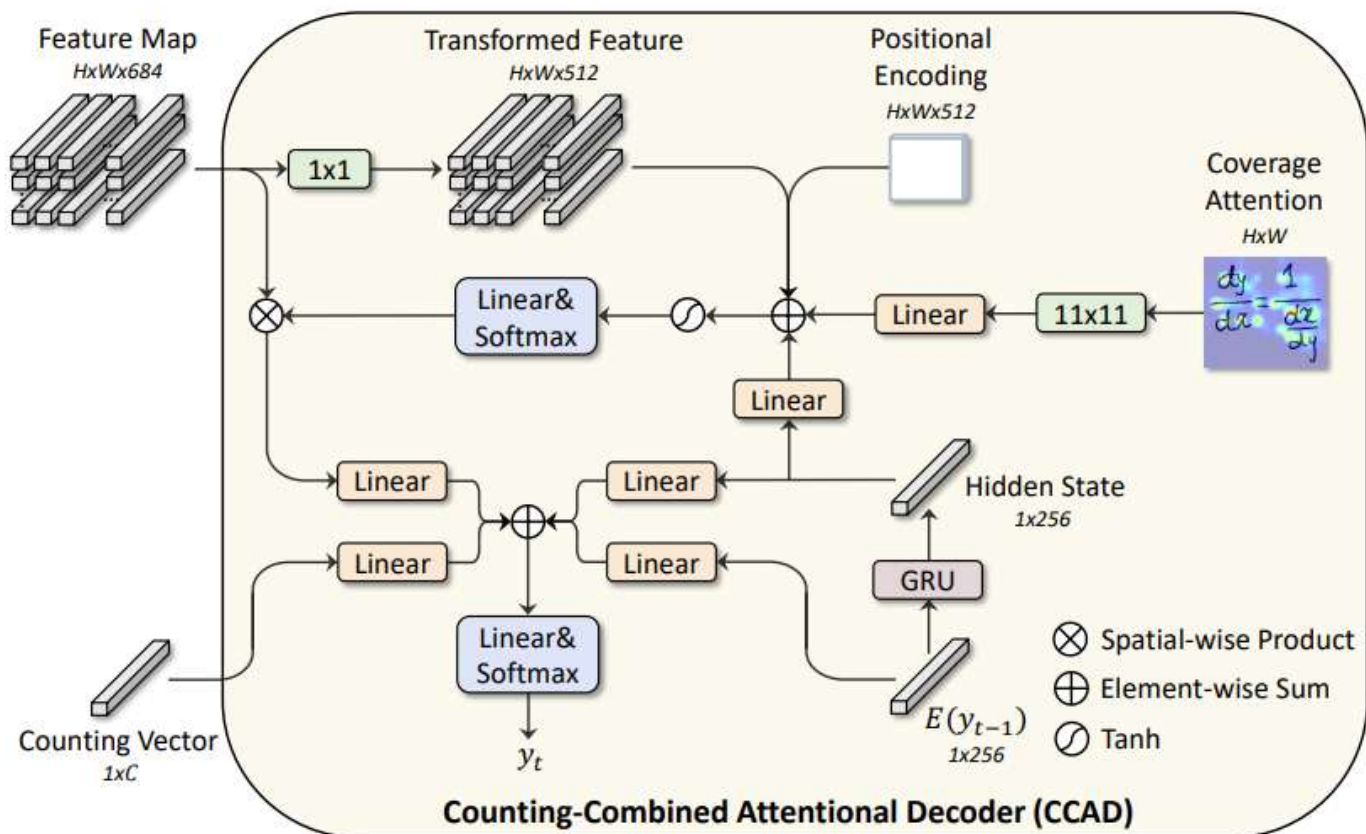

Pseudo Density Map

$$\mathcal{V}_i = \sum_{p=1}^H \sum_{q=1}^W M_{i,pq}$$

Sum Pooling

Counting Vector $1 \times C$

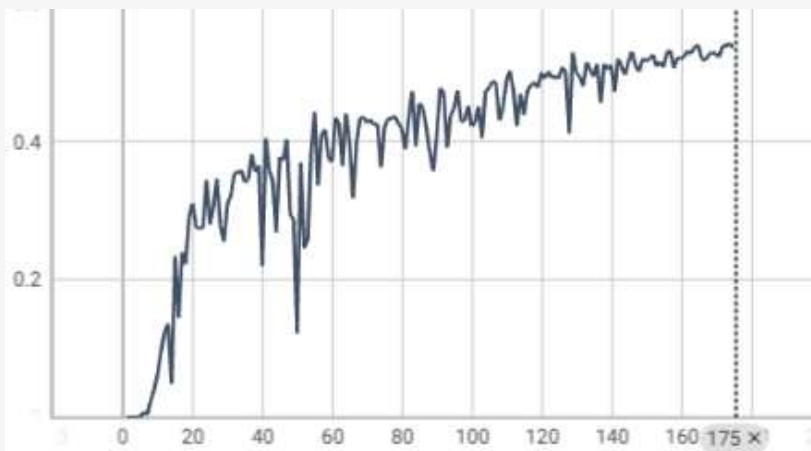

$$p(y_t) = \text{softmax}(w_o^T (W_c C + W_v V + W_t h_t + W_e E) + b_o),$$

$$y_t \sim p(y_t),$$

CAN Replicatioin

Evaluate ExpRate

Evaluate WordRate

Train ExpRate

Train WordRate

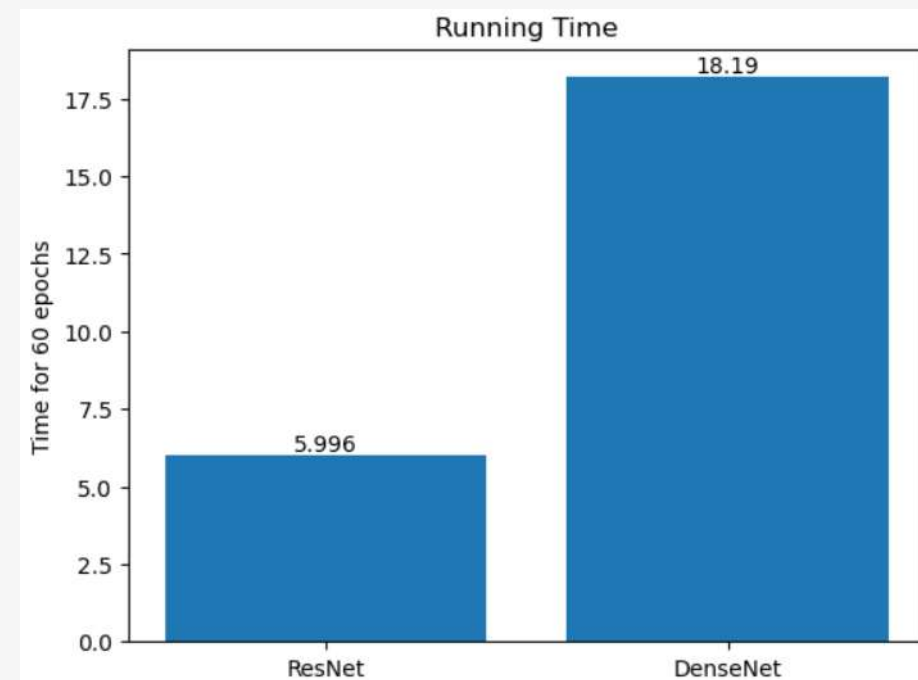

Improvement

🌀 Backbone: DenseNet → ResNet50

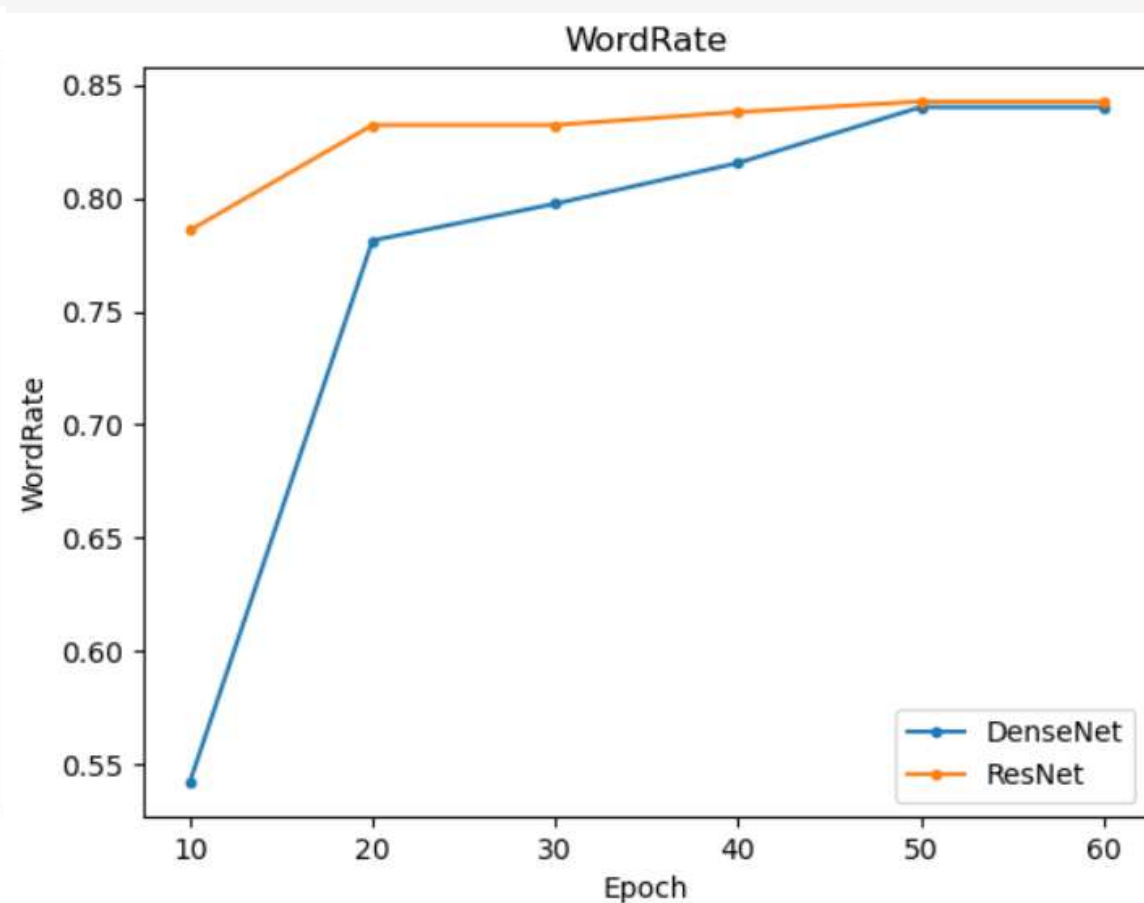

ResNet

Pros: Faster Training and Evaluating Speed
Faster Convergence Speed

Cons: Lower Evaluating ExpRate
Higher Model Complexity(Overfitting)
3M params in DenseNet vs **15M** params in ResNet50

Evaluating
